United Nations Climate Change Conference  
Cancun, December 1, 2010

# outline

- “Hot and dry” – a short introduction to Israel’s southern deserts
- Saline (recycled waste water and groundwater) water resources
- Success stories – three case study crops
  - dates, peppers, olives
- Managing brackish irrigation water
  - The high cost of leaching
  - Environmental responsibility
    - Drainage collection and disposal
    - Desalination
- Conclusions - Can Israel’s experience benefit adaptation approaches for climate change?
  - Sustainable?
  - Appropriate for developing countries?

**United Nations Climate Change Conference**  
**Cancun, December 1, 2010**

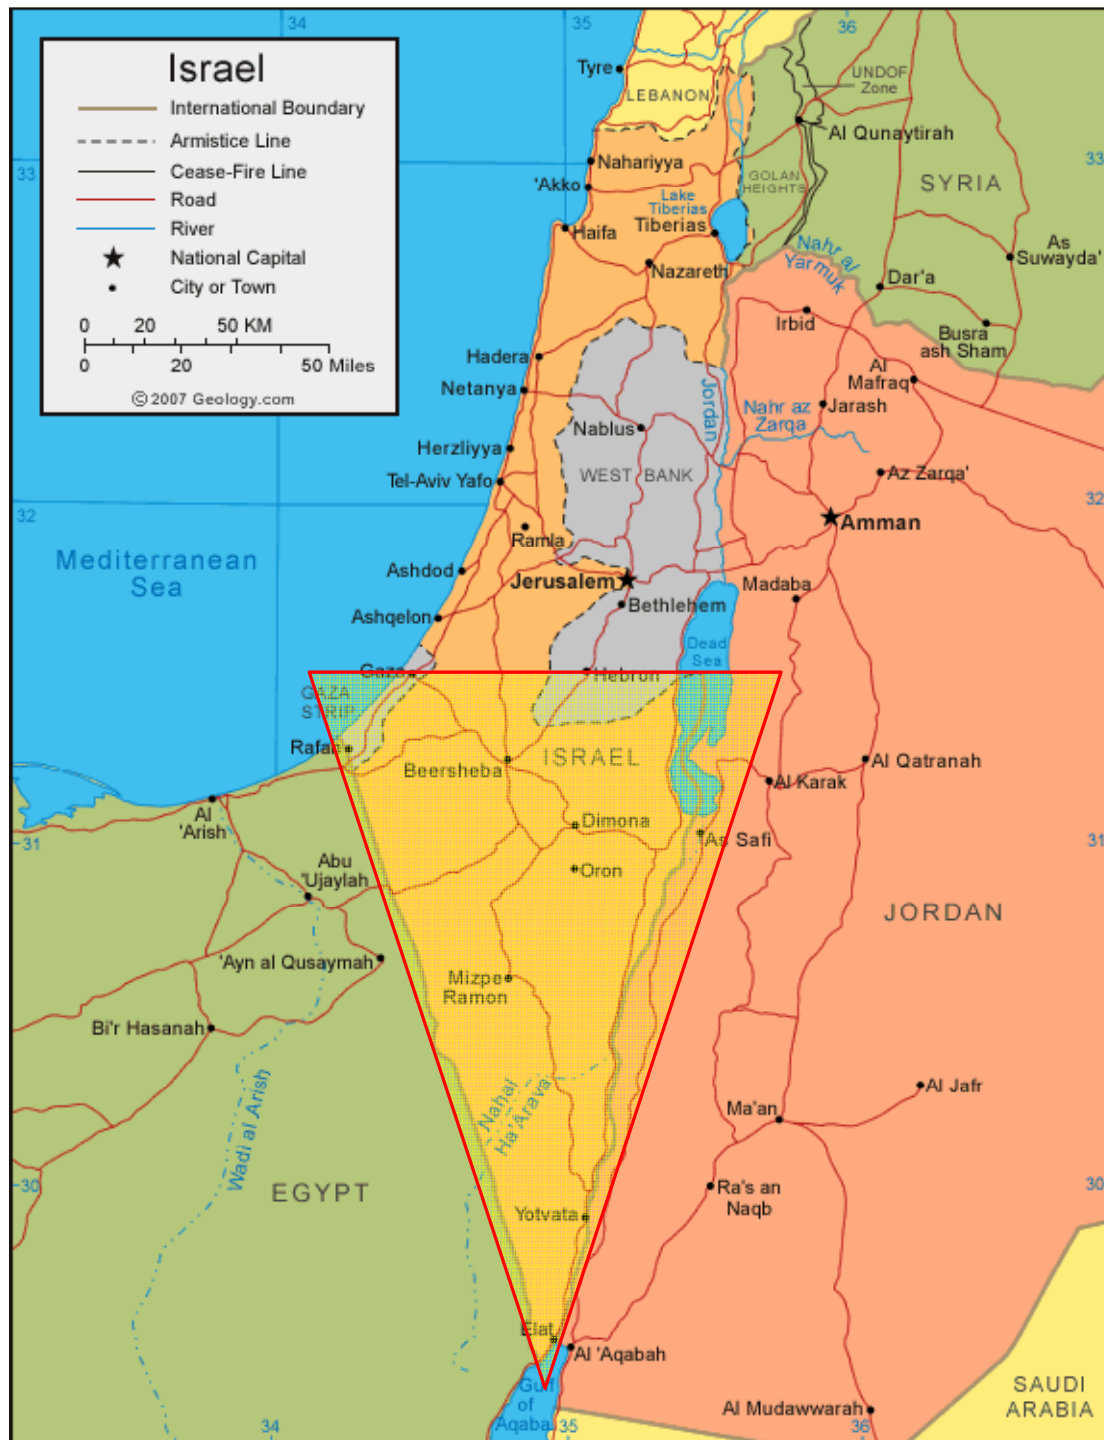

## United Nations Climate Change Conference Cancun, December 1, 2010

# Israel and The Negev

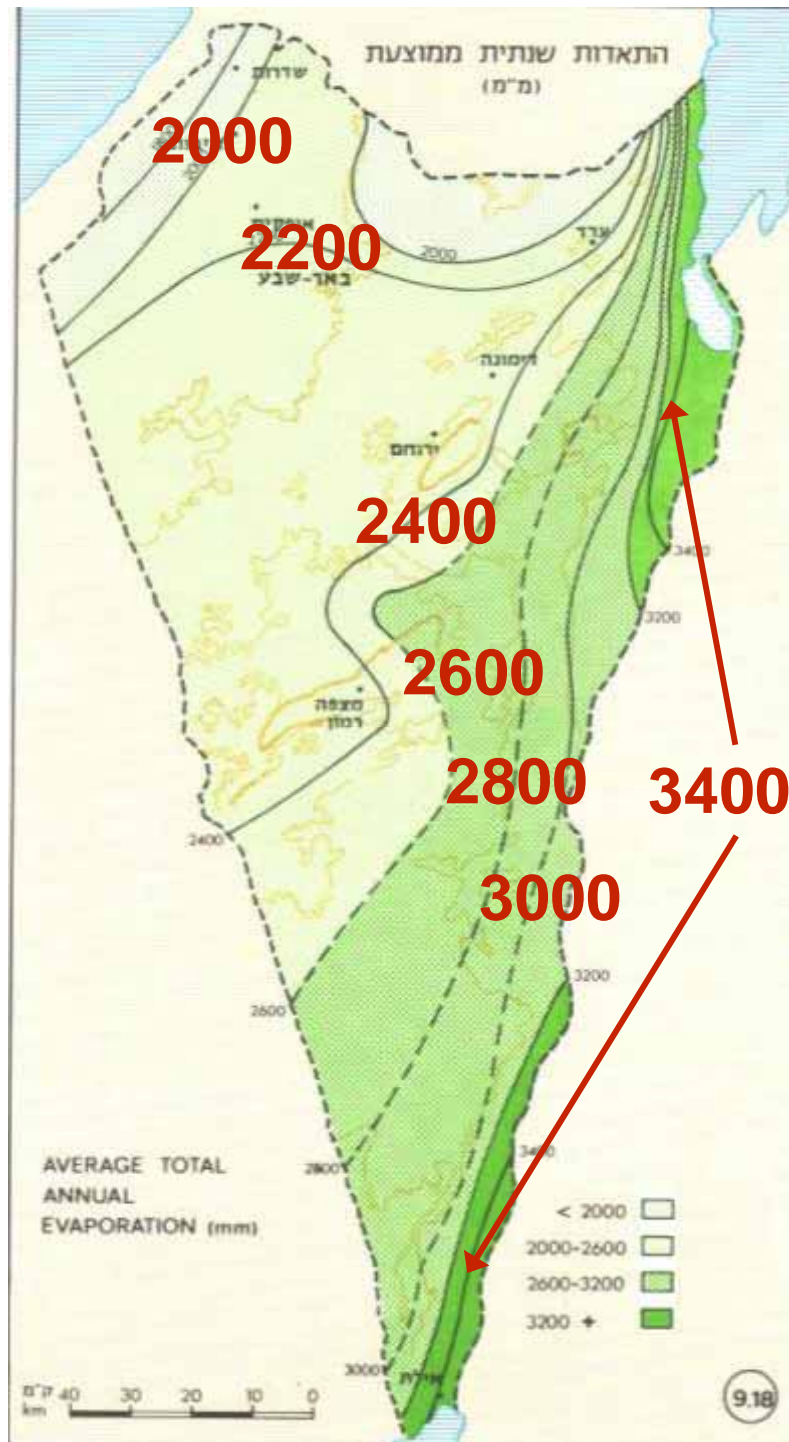

# Israel's Negev desert-rainfall

Annual rainfall (mm)  
Long term averages  
All falls in the winter (Nov-March)

# Israel's Negev desert— potential evaporation

Annual average water loss (mm)

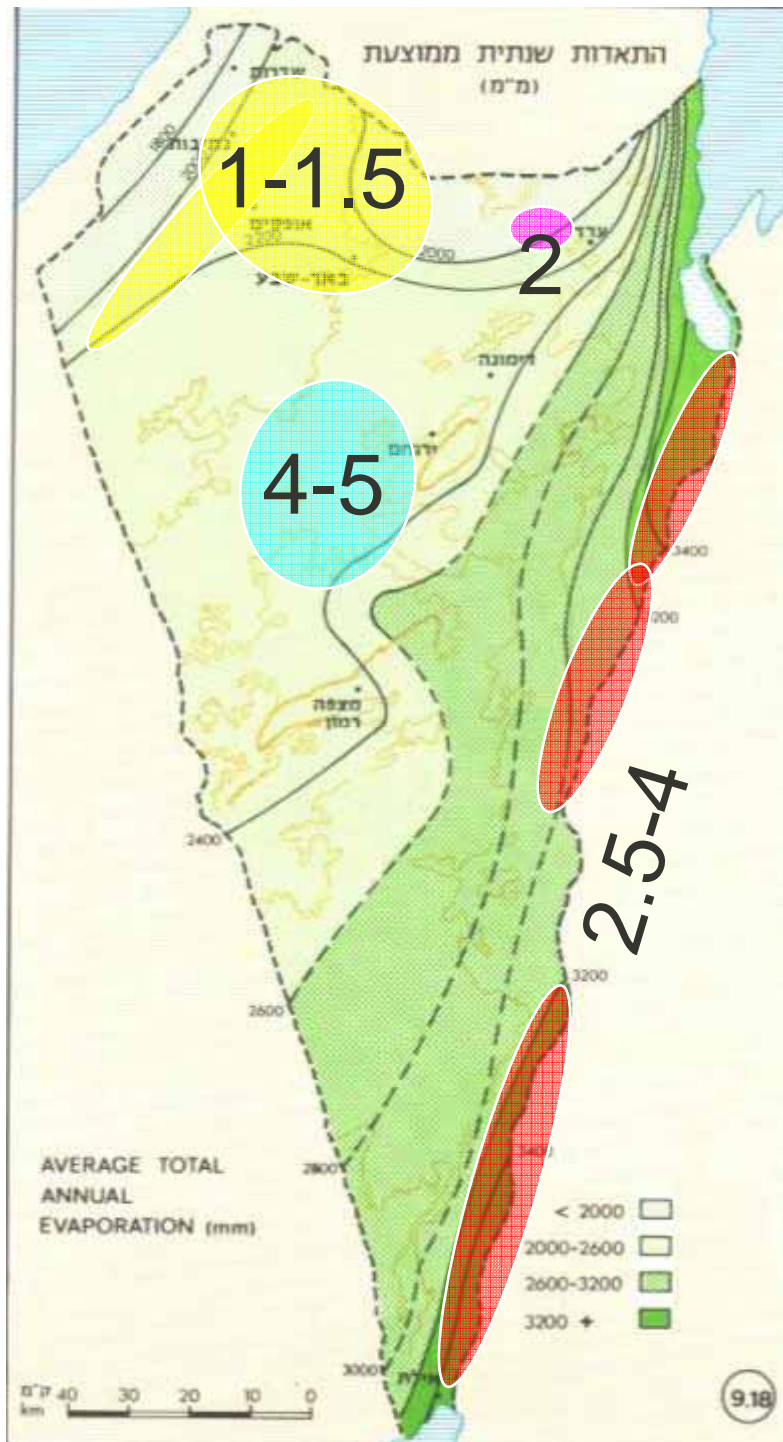

# Irrigation water sources

Electrical conductivity (EC) is a measure of salinity

Good quality water  $< 0.5$  dS/m

Available water in Israel's deserts 1 – 5 dS/m

# Success story #1: Date palms

Native, intensified

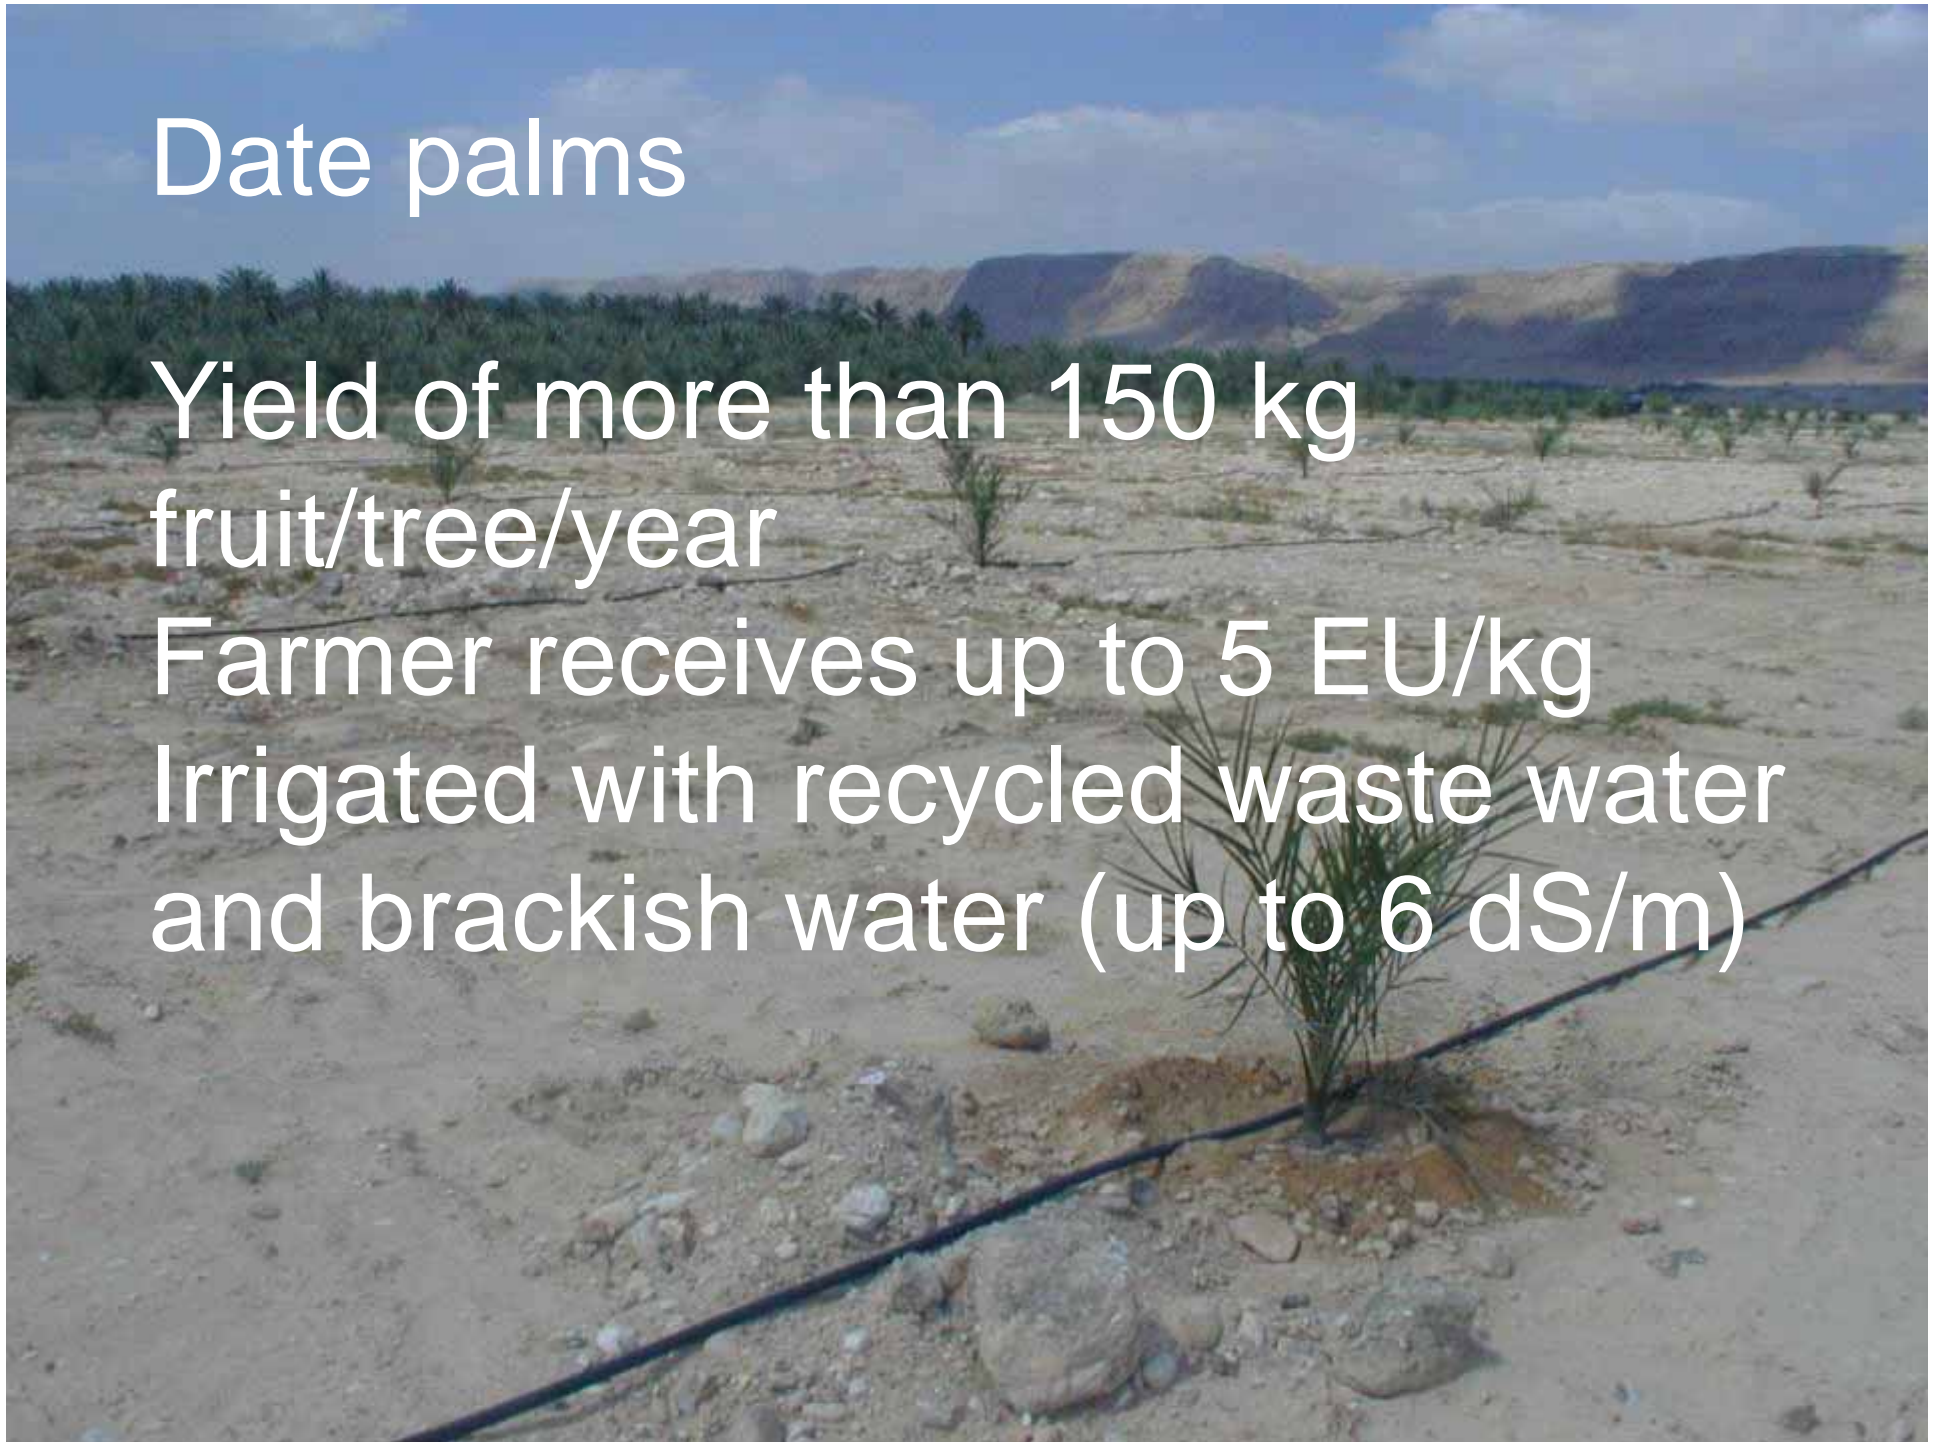

# Date palms

Yield of more than 150 kg  
fruit/tree/year

Farmer receives up to 5 EU/kg

Irrigated with recycled waste water  
and brackish water (up to 6 dS/m)

A photograph of a large-scale commercial greenhouse. The interior is filled with rows of bell pepper plants growing in raised beds. The plants are lush green and appear to be in the early stages of fruiting. The greenhouse structure is made of metal poles and covered with a translucent plastic or polyethylene film. The floor is a light-colored, sandy or dirt surface. The lighting is bright, suggesting a sunny day outside.

## Success story #2: Bell Peppers

No adaptation  
to desert

# Bell peppers

Yields of ~160 tons/ha

Irrigated with brackish (EC 2-4 dS/m)  
ground water

# Success story #3: Olives

Modernization allows movement into deserts

olives

# Olives

- irrigated with recycled wastewater or with brackish groundwater (4-5 dS/m)
- >2,000 L/ha
- stress good for oil quality

## Agricultural success in dry areas and saline water

- Crop choice for economic success – not food supply
- Technologically advanced
  - Excellent growers
- Drip (micro) irrigation

# Drip irrigation

- Partial soil wetting
- Provide plant water and nutrient needs efficiently
- High frequency application
- High water content in root zone + good aeration
- Less concentrations of salts in root zone

## Agricultural success in dry areas and saline water

- Crop choice for economic success – not food supply
- Technologically advanced
  - Excellent growers
- Drip (micro) irrigation
- **Management of salts**

# Increasing salinity causes decreased production

Osmotic “drought”  
Toxic ions

High climatic demand for water + low rainfall

+

Low quality (high salts) available water for irrigation

=

Salt (as NaCl) in a single irrigation season:

pepper in net house in the Central Arava Valley ~6000 kg/Ha

olives in Negev Highlands ~7500 kg/Ha

dates in Southern Arava Valley ~13000 kg/Ha

United Nations Climate Change Conference  
Cancun, December 1, 2010

# Irrigation needs:

# measuring and modeling to evaluate plant water and leaching requirements

## ~~Olives~~ Date palms

Irrigated up to 1,200  
L/day

30-50% more than ET  
needs

## Peppers

Irrigated more than 2X  
Large amounts of water  
climate related demand  
used for leaching in winter

# Sustainable management of salts

- Drainage collection and disposal
- Desalination of water prior to irrigation

United Nations Climate Change Conference  
Cancun, December 1, 2010

## Conclusions: irrigation in the Israel's deserts using brackish water

- Economic success (but not necessarily food security) is possible
  - Technology / investment
  - High value crops
- Consequences of irrigation with saline water
  - Need for leaching of salts
  - Environmental implications
- To be sustainable – salts must be managed
  - Deep percolation of leached salts is environmentally irresponsible –
  - Desalination can be more effective (cost and environmentally) than drainage collection for salt management and has great benefit to agriculture

United Nations Climate Change Conference  
Cancun, December 1, 2010

Conclusions: irrigation in the drylands using brackish water

- Can we apply Israel's achievements towards adaptation measures for those facing increased hot and dry climates?
  - Irrigation will be necessary. Micro-irrigation allows most efficient use of water
  - Sustainable irrigation management?
    - Salinity management
      - Drainage collection and disposal
      - Desalination
  - Relevant to developing regions/economies?
    - Incentives/assistance as economies grow

United Nations Climate Change Conference  
Cancun, December 1, 2010
