

Electricity and climate mitigation

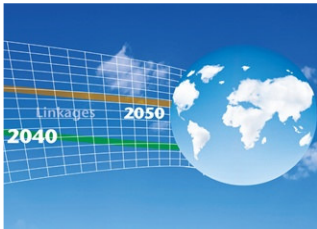

Helle Juhler-Verdoner

Alstom

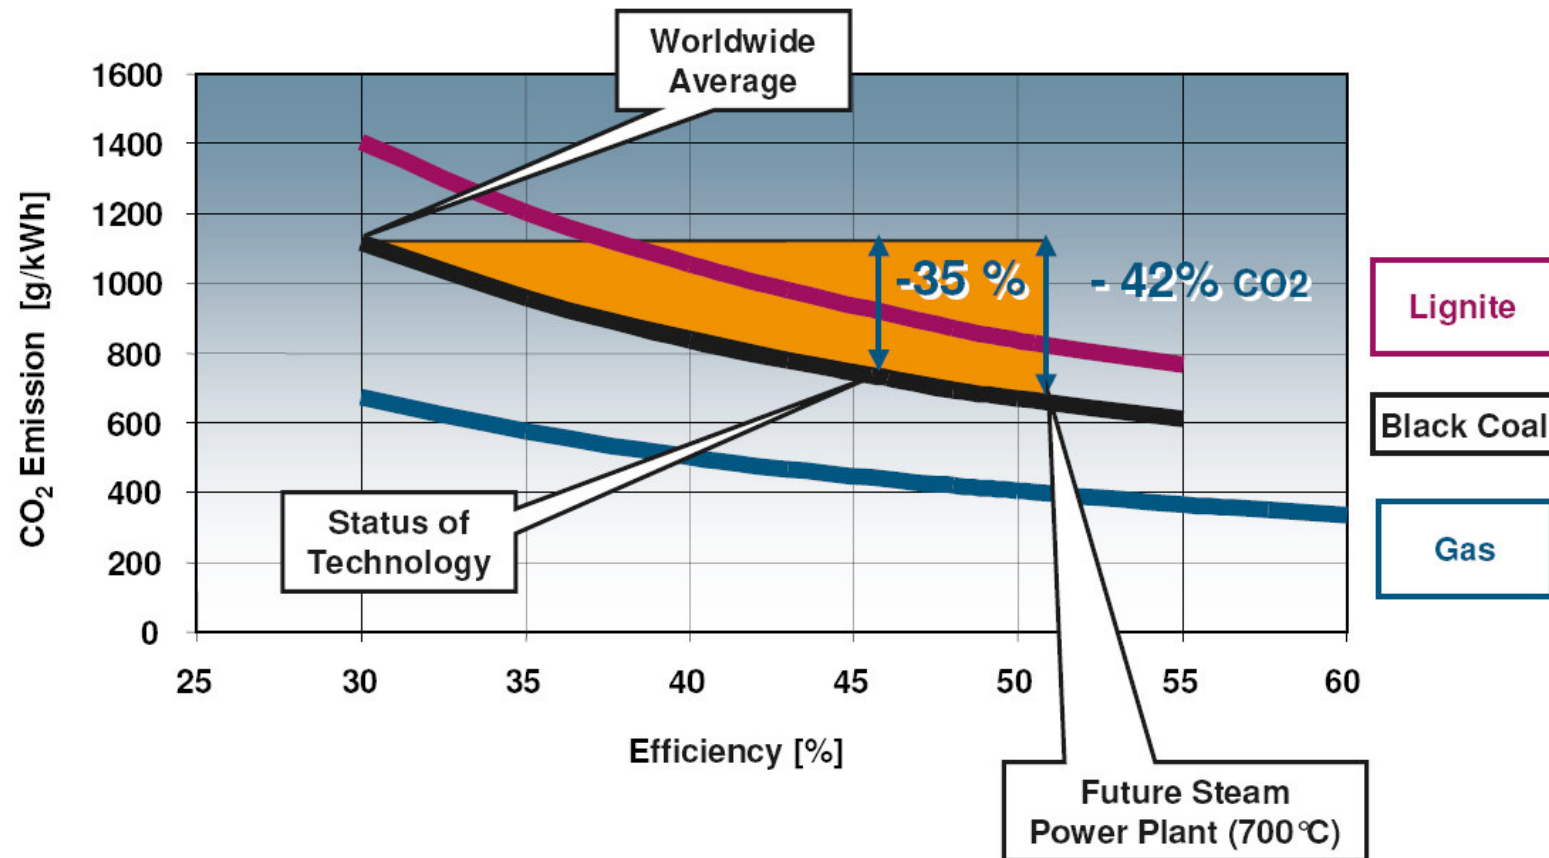

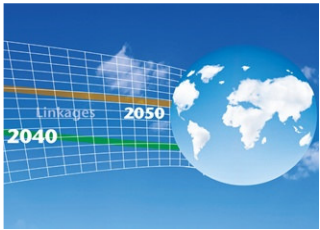

Early retirement of coal fired generation

- ✓ Coal-fired electricity generation contributes a large – and growing – share of global CO2 emissions.
 - ✓ 73% of CO2 from global power generation
 - ✓ 30% of total global CO2 emissions from energy
- ✓ IEA WEO 2010's 450 ppm scenario:
 - ✓ 300 GW of new built coal plants between now and 2035 will be retired before end of their technical lifetime
 - ✓ Around 100 GW will be retired before achieving commercial return
 - ✓ Net loss of **USD 70 bn or 28% of the investment cost**
- ✓ Alternatives to early retirement exist:
 - ✓ **Retrofitting existing plants with more efficient boilers & turbines**
 - ✓ **Carbon Capture and Storage**

How new technology improves energy supply efficiency and reduces CO₂ emissions

Significant CO2 savings could be made

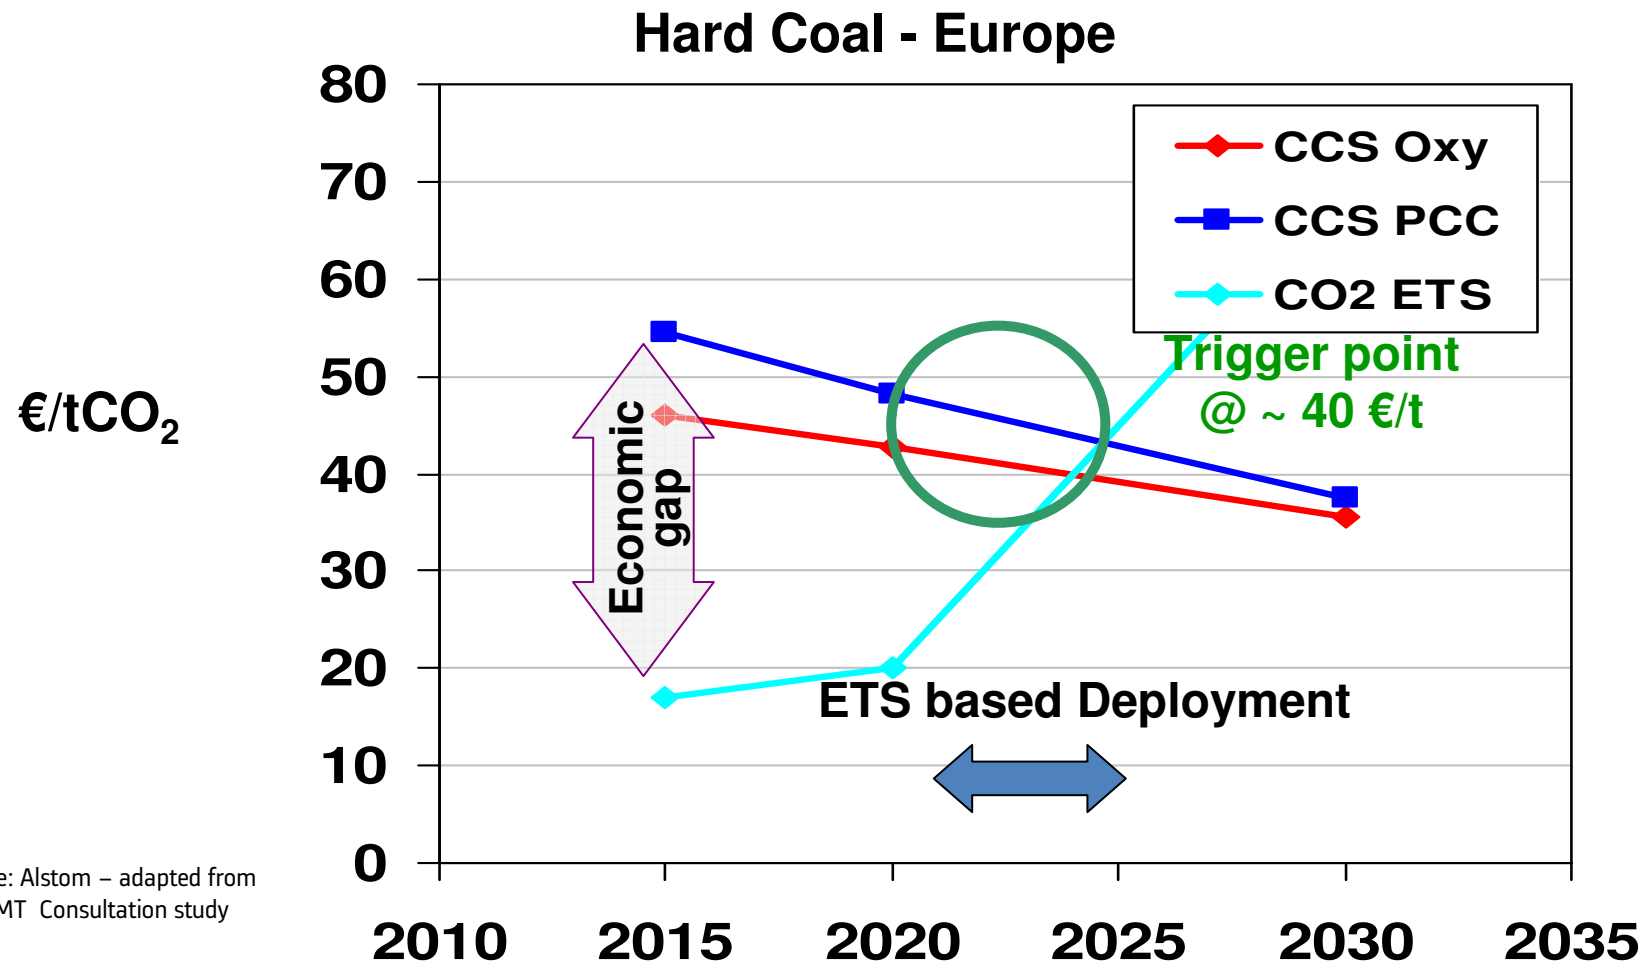

- Even a modest effort to improve efficiency levels could deliver significant CO2 savings.
- E.g. if, **hypothetically**, Europe were to:
 - **retrofit** those **coal plants** aged between 20 and 30 years to improve their efficiency by 3.5 ppt,
 - install BAT on **all new coal plants** ordered now for construction by 2020,
 - **re-power** those **gas fired boiler** plants aged between 20 and 30 years,

then

by 2020 annual power sector CO2 emissions would fall by 29m tonnes a year, equivalent to 12% of EU ETS emissions reductions required by 2020.

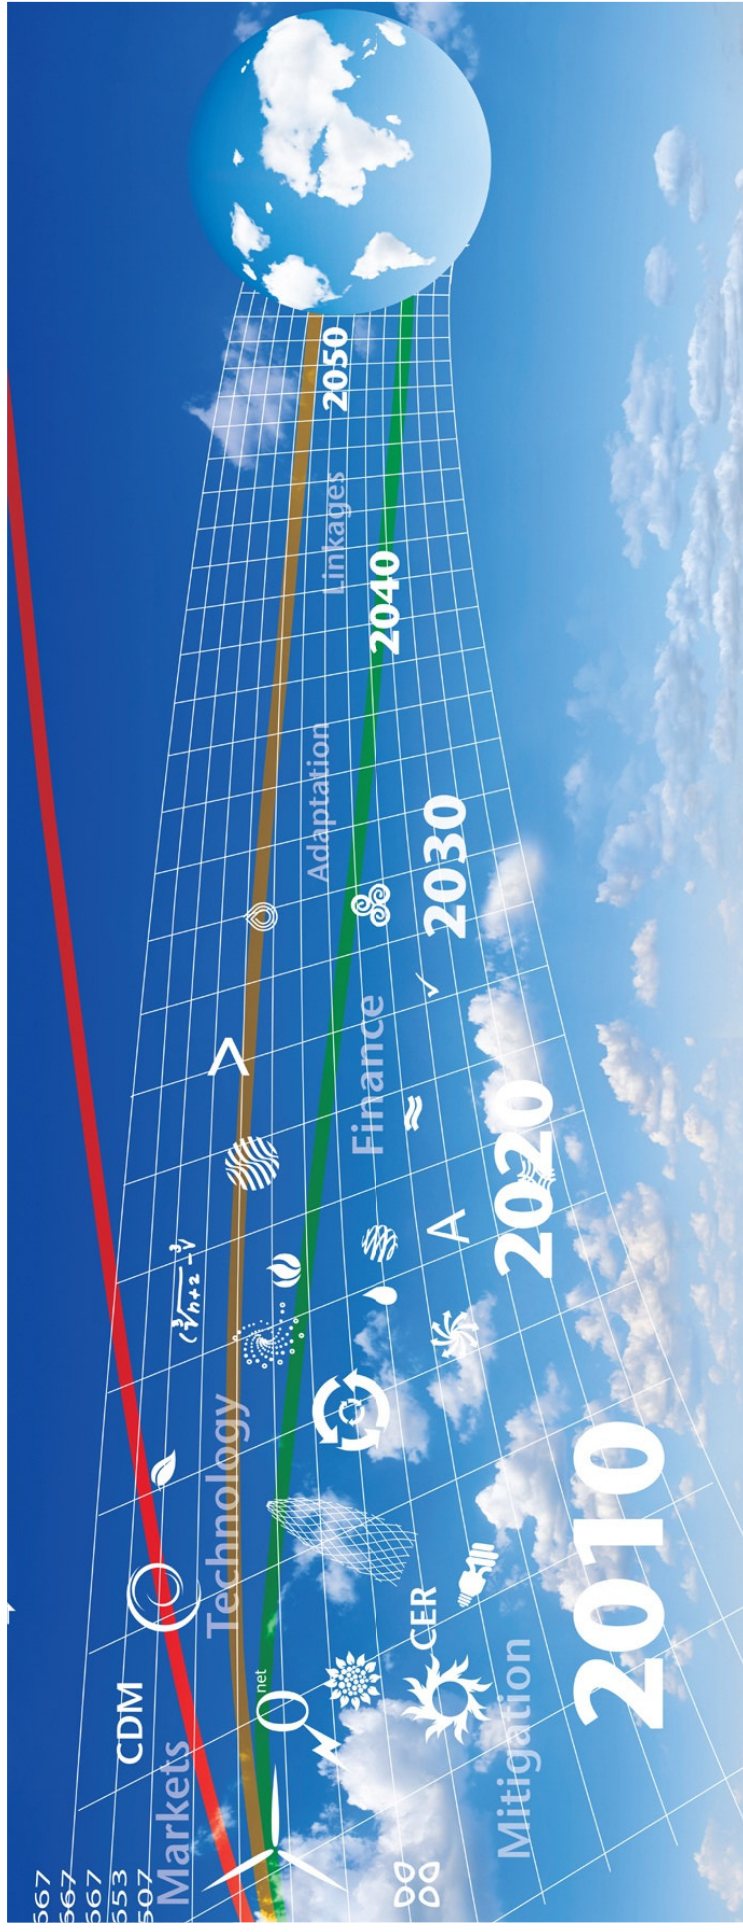

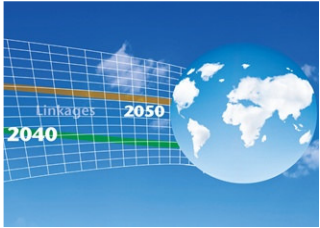

CCS Funding: further support needed

Source: Alstom – adapted from
UK HMT Consultation study

Funding, financing and/or FITs needed in the short and medium term. Including for the current demonstration projects.

Demand-side Energy efficiency

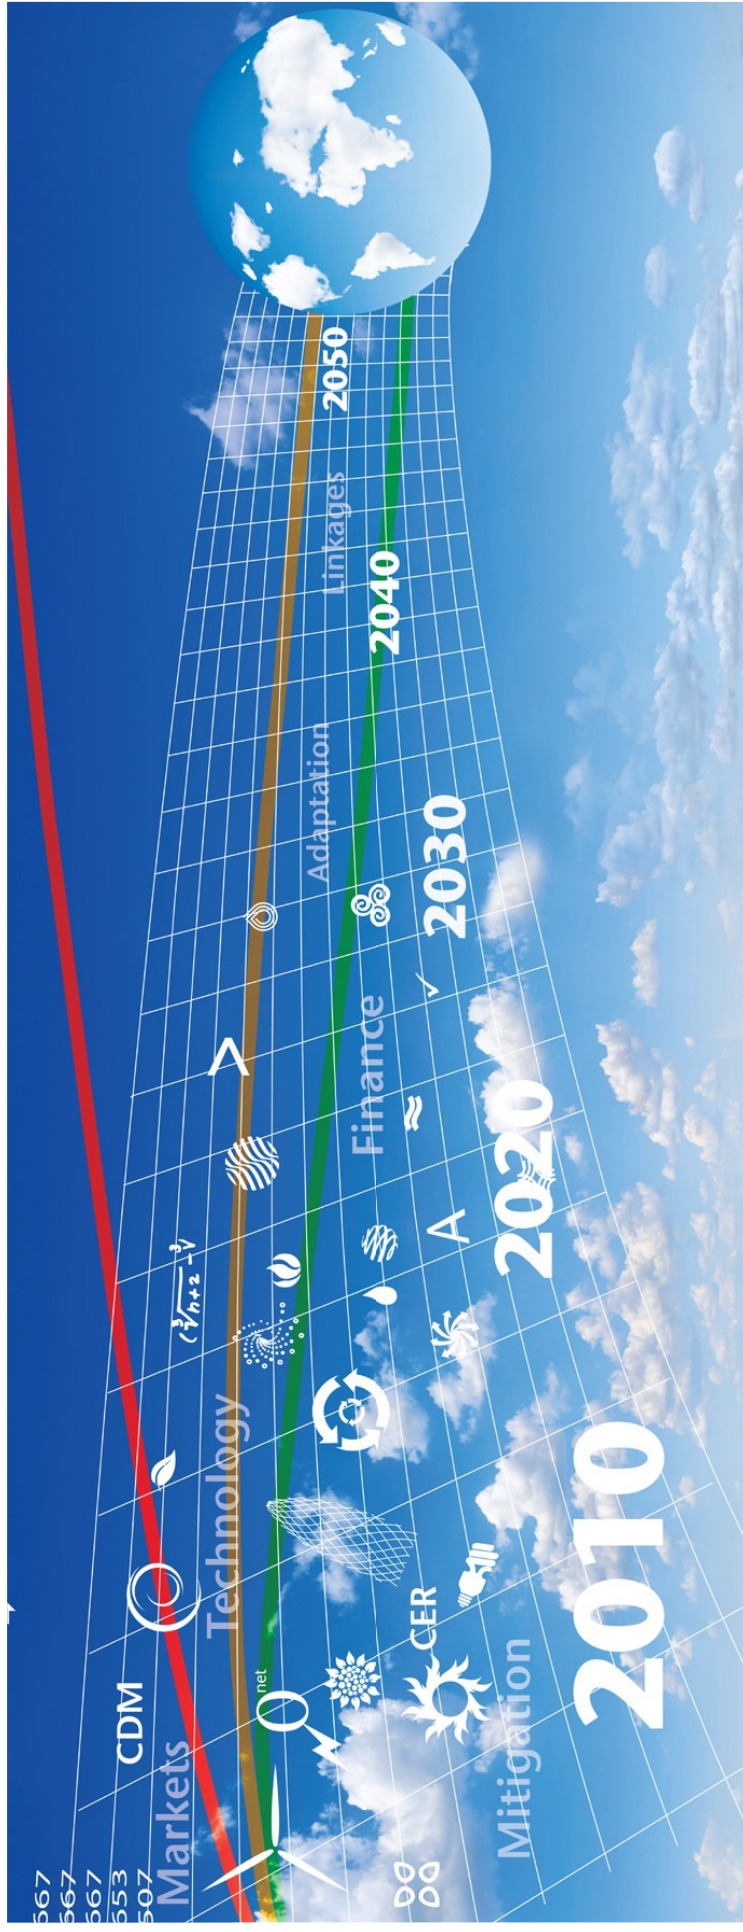

1. Important to address end-user-demand inefficiency

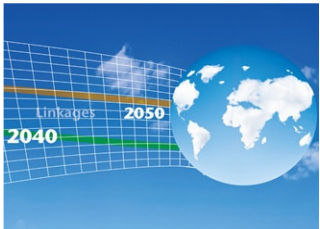

Policies must be adapted to local circumstances (several options)

2. Options also need to address lack of up-front capital

Why do households not implement cost-effective EE?

Can ESCOs or utility programs work?

Electricity market design for decarbonisation

- ✓ All investments need **predictability on financial reward and certainty on the policy framework**
 - delays in policy decision increase electricity prices by 13% (2010-2020, Australian survey)
- ✓ Incentivising low-carbon investments
 - ✓ **Market-wide intervention** (carbon pricing and regulation) better than creating **separate markets** (quantified obligations regulator)
- ✓ Market structures and low-carbon power generation – The real issues are:
 - ✓ Most REs unable to store electricity and fluctuate significantly. Need for back-up capacity
 - ✓ How to reward back-up and fund development of smarter grid?
 - ✓ Support all low-carbon technologies equally - will limit the problem!

Electricity project recommendations*

Every country should introduce policies that realize the potential energy savings through higher efficiency throughout the electricity value chain: generation, grids and end use

Generation

- ✓ Focus on bringing a convincing cost perspective (including capacity building and access to capital) for:
 - **utilizing the highest efficiency technologies** for all new plant construction
 - **restoring design efficiency** in existing plants.
- ✓ E.g Arnot case (South Africa) and hydropower EE **potential between 2 and 5%**

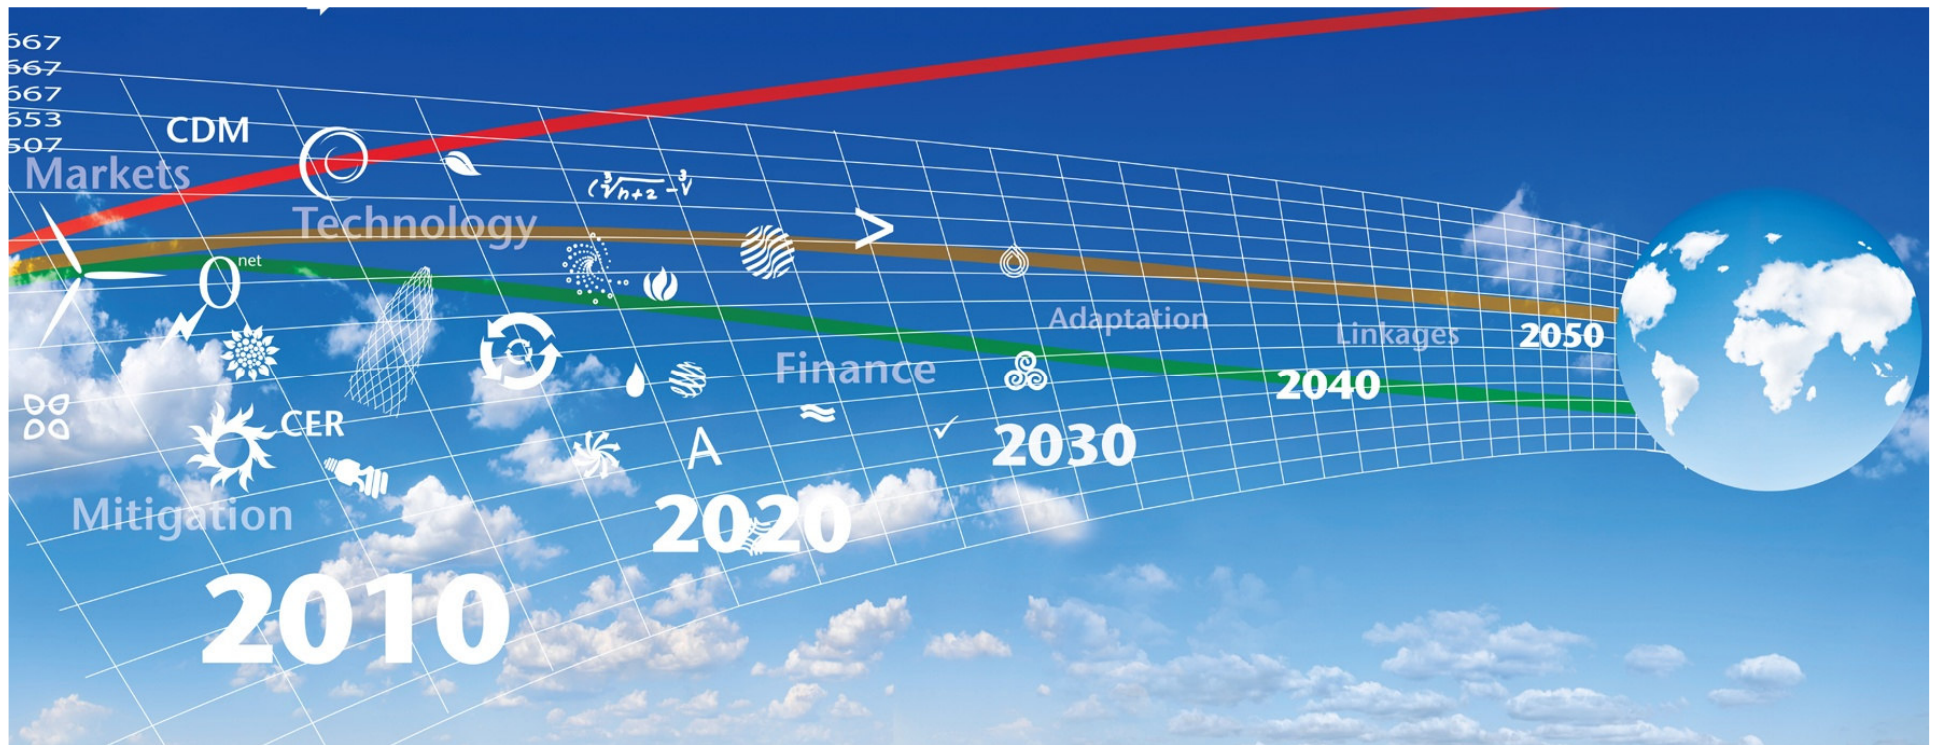

Grid

- ✓ Focus on **recognising investment needs** to increase both efficiency and reliability to:
 - enable intelligent coordination of supply and demand
 - counteract inefficiencies arising from intermittent renewables and increased variability in demand.
 - Introduce smart meters to facilitate energy saving by consumers (but ,more than meters).

End users

- ✓ **Price signals** (energy and carbon) are key to trigger actions in energy efficiency
- ✓ **New energy-saving business models** should be supported as part of an integrated approach to commercial and residential energy efficiency.
- ✓ In **industrial energy efficiency** programs should encourage sector **benchmarking, build capacity to raise efficiency** towards best in class.

Many thanks
